Regression & Gradient Descent

Dr. Shuang LIANG

# Recall: Terminology

- Data
  - Data set, feature, dimensionality, label, sample...
- Train & Test
- Task
  - By prediction target
  - By label

# Recall: Error and Overfitting

- Error rate/Accuracy
  - $E = \frac{\text{the number of misclassified samples } (a)}{\text{the number of all samples } (m)} = \frac{a}{m}$
- Error
  - Train/Test/Generalization error
- Overfitting
  - Small loss on training data, large loss on testing data
  - Can't be avoided completely

# Recall: Evaluation Methods

- Hold-out
- Cross Validation
- Bootstrapping

# Recall: Performance Measure

MSE for Regression

$$E(f; D) = \frac{1}{m} \sum_{i=1}^m (f(\mathbf{x}_i) - y_i)^2$$

Accuracy for Classification

$$\begin{aligned} \text{acc}(f; D) &= \frac{1}{m} \sum_{i=1}^m \mathbb{I}(f(\mathbf{x}_i) = y_i) \\ &= 1 - E(f; D) . \end{aligned}$$

Precision  $P = \frac{TP}{TP + FP}$

Recall  $R = \frac{TP}{TP + FN}$

$$F1 = \frac{2 * P * R}{P + R} = \frac{2 * TP}{\text{the number of samples} + TP - TN}$$

# Recall: Bias and variance

泛化误差与偏差、方差的关系示意图

Large bias	Large variance
Add more features as input	More data
A more complex model	Regularization

**Model**  $y = b + wx_1$  based on domain knowledge

**feature**

$y$ : no. of views on 11/18,  $x_1$ : no. of views on 11/17

$w$  and  $b$  are unknown parameters (learned from data)

**weight**      **bias**

## Step2: Define Loss from Training Data

- Loss is a function of parameters  $L(b, w)$
- Loss: how good a set of values is.

$L(0.5k, 1)$   $y = b + wx_1 \longrightarrow y = 0.5k + 1x_1$  How good it is?

Data from 2017/01/01 – 2020/12/31

## Step2: Define Loss from Training Data

- Loss is a function of parameters  $L(b, w)$
- Loss: how good a set of values is.

$$L(0.5k, 1) \quad y = b + wx_1 \longrightarrow y = 0.5k + 1x_1 \quad \text{How good it is?}$$

Data from 2017/01/01 – 2020/12/31

## Step2: Define Loss from Training Data

- Loss is a function of parameters  $L(b, w)$
- Loss: how good a set of values is.

Loss: 
$$L = \frac{1}{N} \sum_n e_n$$

$e = |y - \hat{y}|$        $L$  is mean absolute error (**MAE**)

$e = (y - \hat{y})^2$        $L$  is mean square error (**MSE**)

If  $y$  and  $\hat{y}$  are both probability distributions ➡ Cross-entropy

## Step2: Define Loss from Training Data

- Loss is a function of parameters  $L(b, w)$
- Loss: how good a set of values is.

**Model**  $y = b + wx_1$

# Step3: Optimization

## Gradient Descent 梯度下降

In 1-dimension, the derivative of a function:

$$\frac{df(x)}{dx} = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

In multiple dimensions, the gradient is the vector of (partial derivatives) along each dimension. The slope in any direction is the dot product of the direction with the gradient.

**The direction of steepest descent is the negative gradient.**

# Practice

**Try to calculate the gradient!**

$$f(x_1, x_2, x_3) = \ln(1 + \exp(-2x_1 + 3x_2 - 4x_3))$$

# Today's Topics

- Regression
- Linear Regression
- ***Gradient Descent***
- Regularization

# Gradient Descent

$$w^* = \arg \min_w L$$

- (Randomly) Pick an initial value  $w^0$
- Compute  $\frac{\partial L}{\partial w} \big|_{w=w^0}$

# Gradient Descent

$$w^* = \arg \min_w L$$

➤ (Randomly) Pick an initial value  $w^0$

➤ Compute  $\frac{\partial L}{\partial w} \big|_{w=w^0}$

$$w^1 \leftarrow w^0 - \eta \frac{\partial L}{\partial w} \big|_{w=w^0}$$

# Gradient Descent

$$w^* = \arg \min_w L$$

➤ (Randomly) Pick an initial value  $w^0$

➤ Compute  $\frac{\partial L}{\partial w} \big|_{w=w^0}$

$$w^1 \leftarrow w^0 - \eta \frac{\partial L}{\partial w} \big|_{w=w^0}$$

➤ Update  $w$  iteratively

# Gradient Descent

$$w^*, b^* = \arg \min_{w, b} L$$

- (Randomly) Pick initial values  $w^0, b^0$
- Compute

$$\begin{aligned} \frac{\partial L}{\partial w} \Big|_{w=w^0, b=b^0} \\ \frac{\partial L}{\partial b} \Big|_{w=w^0, b=b^0} \end{aligned}$$

$$w^1 \leftarrow w^0 - \eta \frac{\partial L}{\partial w} \Big|_{w=w^0, b=b^0}$$

$$b^1 \leftarrow b^0 - \eta \frac{\partial L}{\partial b} \Big|_{w=w^0, b=b^0}$$

Can be done in one line in most deep learning frameworks

- Update  $w$  and  $b$  iteratively

# Gradient Descent

$$\text{Model } y = b + wx_1$$

$$w^*, b^* = \arg \min_{w, b} L$$

# Learning Rate

$$\theta^i = \theta^{i-1} - \eta \nabla L(\theta^{i-1})$$

Set the learning rate  $\eta$  carefully

If there are more than three parameters, you cannot visualize this.

# Gradient Descent

Tip 1: Adaptive Learning Rate

# Adaptive LR

## Adagrad

$$w^{t+1} \leftarrow w^t - \frac{\eta}{\sqrt{\sum_{i=0}^t (g^i)^2}} g^t$$

- Popular & Simple Idea: Reduce the learning rate by some factor every few epochs.
  - At the beginning, we are far from the destination, so we use larger learning rate
  - After several epochs, we are close to the destination, so we reduce the learning rate
  - E.g. 1/t decay:  $\eta^t = \eta / \sqrt{t + 1}$
- Learning rate cannot be one-size-fits-all
  - Giving different parameters different learning rates

# Gradient Descent

Tip 2: Stochastic Gradient Descent

# Stochastic Gradient Descent (SGD)

$$L = \sum_n \left( \hat{y}^n - \left( b + \sum w_i x_i^n \right) \right)^2$$

Loss is the summation over all training examples

◆ Gradient Descent  $\theta^i = \theta^{i-1} - \eta \nabla L(\theta^{i-1})$

◆ Stochastic Gradient Descent

Faster!

Pick an example  $x^n$

Loss for only one example

$$L^n = \left( \hat{y}^n - \left( b + \sum w_i x_i^n \right) \right)^2 \quad \theta^i = \theta^{i-1} - \eta \nabla L^n(\theta^{i-1})$$

# SGD

## Gradient Descent

Update after seeing all examples

## Stochastic Gradient Descent

Update for each example  
If there are 20 examples,  
20 times faster.

# Gradient Descent

Tip 3: Feature Scaling

# Feature Scaling

$$y = b + w_1x_1 + w_2x_2$$

Make different features have the same scaling

# Feature Scaling

$$y = b + w_1x_1 + w_2x_2$$

# Feature Scaling

For each  
dimension  $i$ :  
mean:  $m_i$   
standard  
deviation:  $\sigma_i$

$$x_i^r \leftarrow \frac{x_i^r - m_i}{\sigma_i}$$

The means of all dimensions are 0,  
and the variances are all 1

# Gradient Descent Limitation

So far, we've got optimization

Let's go back to the machine learning framework.

# Machine Learning is so simple .....

$$w^* = 0.97, b^* = 0.1k$$

$$L(w^*, b^*) = 0.48k$$

$y = 0.1k + 0.97x_1$  achieves the smallest loss  $L = 0.48k$  on data of 2017 – 2020 (**training data**)

How about data of 2021 (**unseen during training**)?

$$L' = 0.58k$$

# The result

# Linear Regression Summary

**Model**  $y = b + wx_1$

**Loss**  $e = |y - \hat{y}|$   $L$  is mean absolute error (**MAE**)  
 $e = (y - \hat{y})^2$   $L$  is mean square error (**MSE**)

**Optimization** Gradient Descent

# Linear Regression Summary

- **Strength & Weakness**

- ✓ Easy to understand and implement
- ✓ Good comprehensibility
- × Performs poorly when there are non-linear relationships
- × Not flexible enough to capture more complex patterns

# Today's Topics

- Regression
- Linear Regression
- Gradient Descent
- *Regularization*

# Recall: What to do with large variance?

- More data

Very effective,  
but not always  
practical

10 examples

100 examples

- *Regularization*

# Regularization

- Complex model leads to overfitting. Regularization is a way to mitigate this undesirable behavior.
- Through regularization, we can *penalize* complex models and favor simpler ones.

$$\min_w \mathcal{L}(w) + \Omega(w)$$

- The second term  $\Omega$  is a regularizer, measuring the complexity of the model given by  $w$ .

# Regularization intuition: Prefer Simpler Models

Regularization pushes against fitting the data  
*too* well so we don't fit noise in the data

# Regularization

- L2 Regularization

$$\Omega(\mathbf{w}) = \lambda \|\mathbf{w}\|_2^2$$

Here the main effect is that large model weights  $w_i$  will be **penalized** (avoided), since we consider them “unlikely”, while small ones are ok.

*where*  $\|\mathbf{w}\|_2^2 = \sum_i w_i^2$

**Example:** ridge regression --> MSE + L2 Regularization

$$\min_{\mathbf{w}} \quad \frac{1}{2N} \sum_{n=1}^N [y_n - \mathbf{x}_n^\top \mathbf{w}]^2 + \lambda \|\mathbf{w}\|_2^2$$

# Regularization

- **L1 Regularization**

$\Omega(w) = \lambda \|w\|_1$  For the L1-regularization the optimum solution is likely going to be **sparse** (only has few non-zero components) compared to the case where we use L2-regularization.

*where*  $\|w\|_1 = \sum_i |w_i|$

**Example:** lasso regression --> MSE + L1 Regularization

$$\min_{\mathbf{w}} \quad \frac{1}{2N} \sum_{n=1}^N [y_n - \mathbf{x}_n^\top \mathbf{w}]^2 + \lambda \|\mathbf{w}\|_1$$

# Regularization

- **L0 Regularization**

$$\Omega(w) = \lambda \|w\|_0$$

*where*  $\|w\|_0 = \sum_i |w_i|^0$

- Feature selection can also be achieved by using the number of non-zero parameters.
- However, L1 regularization is generally used, because the L0 norm is an NP-hard problem, and it is difficult to find the optimal solution.

# L1 VS L2

- **Both** can help reduce the risk of overfitting
- **L2 Regularization** tends to distribute weights evenly among related features
- **L1 Regularization** tends to select one from the relevant features, and the rest of the feature weights decay to zero (*Feature Selection*)

L1 regularization is easier to obtain ***sparse solutions*** than L2 regularization

# L1 VS L2 : Case Study

$$x = [1, 1, 1, 1]$$

$$w_1 = [1, 0, 0, 0]$$

$$w_2 = [0.25, 0.25, 0.25, 0.25]$$

Which of  $w_1$  or  $w_2$  will the L2 regularizer prefer?

$$w_1^T x = w_2^T x = 1$$

# L1 VS L2 : Case Study

$$x = [1, 1, 1, 1]$$

$$w_1 = [1, 0, 0, 0]$$

$$w_2 = [0.25, 0.25, 0.25, 0.25]$$

Which of  $w_1$  or  $w_2$  will the L1 regularizer prefer?

$$w_1^T x = w_2^T x = 1$$

# Summary
